

HPHT Wellbore Stability & Influx Management Guidelines

Section: Pore Pressure & Hydrostatic Balance

Page 1 of 1 - GeoInsight-RigX Historical Archives

Accurate pore pressure prediction and real-time kick detection are paramount during development drilling across depleted sandstone reservoirs.

Differential pressure across the drill bit must not exceed 350 psi in high-porosity intervals to mitigate differential sticking risk.

Continuous monitoring of pit volume totals, flow paddles, and mud temperature gradients provides early warning of impending kicks or fracture-induced fluid loss.
